# **Microsoft Movie Analysis**

Author: Bridget Carson

# **Overview**

The movie industry in the U.S.A and Canada was worth 7.37 billion USD in 2022, down from its peak of 11.89 billion USD in 2019 before the COVID pandemic.

(https://www.statista.com/statistics/187069/north-american-box-office-gross-revenue-since-1980/ (https://www.statista.com/statistics/187069/north-american-box-office-gross-revenue-since-1980/))

Microsoft is considering entering the movie production market and is seeking actionable insights into how to make a successful entry.

### **Business Problem**

Microsoft is looking to enter the movie production industry. Microsoft's main pain points are lack of experience in the movie industry as well as the high competition the business will face. To reduce the risks associated with entering this market, 3 recommendations will be presented based on past movie data for Microsoft to be successful entering the movie industry.

As the main objective of any business venture is financial success, the key target variable is revenue. The most important data analysis questions relate to which factors will maximise the chance of a financially successful entry to the market.

These questions are important from a business perspective as the commercial viability of any business venture is paramount, and therefore considering factors which will increase movie revenue will help with a successful launch.

# **Data Understanding**

The data is information relating to movie releases between 2000 and 2019. This is relevant as past movie performance enables Microsoft to understand how successful movies were made. This can assist making decisions for their movie production.

Initially, I focused on the provided datasets for analysis. However, however I found these to be limiting as the TN Movie Budget file (which included budget and release month) did not contain IMDB numbers. This meant merging with other datasets on the movie title, which was not precise as a small difference in puncutation or abbreviations meant that data was missed or counted twice.

I found a further movie dataset on Kaggle

(https://www.kaggle.com/datasets/rounakbanik/the-movies-dataset (https://www.kaggle.com/datasets/rounakbanik/the-movies-dataset)) which contained IMDB numbers as well as the variables I wanted to include (release month, revenue and budget), and therefore the Kaggle dataset was the basis for analysis.

The limitation with the Kaggle dataset was the most recent entry was 4th Aug 2017. The TN Movie Budgets file had entries up to 2019. Therefore I merged the merged the titles between these dates into the Kaggle set.

The final dataset includes 3,435 movies including movie name, release date, gross income, production costs, votes. This was then merged with directors and writers for key people analysis.

The target variable is revenue. Although there are websites collecting ratings, businesses require commercial success for new ventures. Further, there is a low correlation (correlation coefficient of 0.21) between worldwide gross revenue and average rating from IMDB.

Therefore revenue will be focused on

I have focused on worldwide revenue as 36% of the movie revenue is from revenue from outside USA & Cananda (based on the TN Movie Budgets data which broke down domestic & worldwide revenue). This is significant enough to include and therefore worldwide revenue is the target variable.

Using the production budget, I also calculated movie profit. There is a very high correlation (correlation coefficient of 0.98) between the revenue and profit, so either revenue or profit could be used for analysis. Therefore I used worldwide revenue.

With worldwide revenue as the target variable, the analysis focused on finding recommendations which were correlated with higher revenue. The variables which were focused on genre, month of release and recommended director and writer.

# **Data Preparation**

My process for preparing the data was to enable to highest number of movies with the target variables. These were revenue, release month, genre and people. As I focused on worldwide revenue, domestic revenue was dropped.

Data from 6 data sets were used, which required cleaning to enable merging. There was a small number of missing data in the final set in columns for number of votes and average votes, which I filled with the average. For missing values in budget, revenue or genre the rows were dropped, as this information cannot be estimated effectively.

Having found run time and votes were not positively correlated to revenue, these were later dropped as well.

As Microsoft would be interested in bigger budget productions, movies with revenue or budget below \$ 10,000 were dropped.

The final dataset was 3429 movies.

One limitation of the data is that it is right-skewed, due to a large number of movies with small revenue and a smaller number with large revenue. When plotted, there are many movies considered 'outliers'. These were kept as there are a large number, and removing them would take away insights into the highest grossing movies. Further, as Microsoft would have the ability to make large budget movies, the analysis should retain these high grossing movies to gain insights into their success.

# **Data Modeling**

Once I created the dataset, I used a scatter matrix to look for correlation between variables. The most positively correlated variables were revenue and profit, as well as revenue and budget. There was no significant correlation with run time or average votes.

Looking for the most successful genre required using the explode function to turn the list of genres into rows. The revenue for each genre was then grouped and summed to give a list of genres by revenue.

Next I filtered on the most successful genres, and grouped the average revenue of key people in the dataset to find the most successful director and writer who had worked in these genres.

Lastly I used the release month to find the most profitable month to launch movies for these genres. This was done by grouping the average revenue by month. The average revenue was most appropriate as total revenue per month was skewed by the months with the highest number of launches.

Initally I focused on these questions using the provided data, however the limitations of these resulted in 1800 movies to be analysed. Using the dataset from Kaggle meant I could exand the time frame back to 2000 as well as using the IMDB number for more accurate merging. Using this approach increased the dataset to 3429.

Although this is not a large database, these choices were appropriate to address the business problem, as the final dataset contained movies with the variables I wanted to focus on - revenue, release month, genres and people. These became particularly important when the low correlation of run time and average vote became apparent.

```

# **Evaluation**

From the data there are actionable insights for Microsoft to enable a successful launch into the movie production industry.

Genre is one movie element where there is a large disparaty in revenue results. Adventure and Action films achieved the highest revenue results. Given that many movies are considered both Action and Adventure, this result could be from the same movies being counted in both these genres. However, there is a clear advantage on focusing on these genres for financial success.

Knowing the most successful genres, Microsoft can hire the most successful key people in these genres. This is recommended due to Microsoft not having movie production experience, the expertise of these successful people could be utilised. These people will be

expensive, but as there is a high correlation between revenue and budget, investing in these people and a high budget for the movie overall would increase the probability of financial success.

Release month is a variable where there are clear months favouring higher revenue. Timing for movie release for the US summer and the Christmas period would increase the chance of movie success for ,ovies in the Adventure and Action genres. This result could be skewed

# **Conclusions**

From these results, I would recommend the following to Microsoft -

- 1 Focus on movies in the Adventure and/or Action genres. Movies in these genres are significantly more financially successful than other genres.
- 2 Hire the most successful key people from Adventure or Action movies. The most successful writer in both Adventure and Action is Nicole Perlman. The most successful director in Adventure is Rich Moore and in Action it is Clint Eastwood.
- 3 Aim to release movies coinciding with the US summer period (May/June) or the Christmas period (Nov/Dec) as these are the most financial success times for Adventure and Action movies.

While these recommendations will improve the likelihood of financial success, there will be huge competition in this business venture and require the raising of large amounts of funds for covering production budgets. Further, some of the most successful movies in recent time are franchises (e.g. Marvel), which Microsoft does not own.

This was a small dataset and therefore further information would be helpful to create a larger dataset with the required variables to continue analysing the movie industry.
